Installation, Operation and Maintenance Instructions

SUSPENDED ELECTROMAGNETS

ERIEZ MAGNETICS HEADQUARTERS: 2200 ASBURY ROAD, ERIE, PA 16506-1402 U.S.A.
WORLD AUTHORITY IN SEPARATION TECHNOLOGIES
Introduction

This manual applies to the two basic types of Eriez Magnetics suspended electromagnets: oil cooled and air-cooled. The slight differences in installation and maintenance procedures for these magnets are detailed in the text.

A careful reading of these Installation, Operation and Maintenance Instructions will assure your magnet's most efficient and dependable performance.

If there are any questions or comments about the manual, please call Eriez Manufacturing at 814/835-6000 for assistance.

⚠️ CAUTION - STRONG MAGNET

This equipment includes one or more extremely powerful magnetic circuits. The magnetic field may be much stronger than the Earth's background field at a distance several times the largest dimension of the equipment.

- If you use a heart pacemaker or similar device you must never approach the equipment because your device may malfunction in the magnetic field, with consequences up to and including death.

- To avoid serious pinch-type injuries caused by objects attracted to the magnet, keep all steel and iron objects well away from the equipment. Do not allow hands, fingers, and other body parts to be caught between the equipment and “workpiece” being lifted.

- Keep credit cards, computer disks, and other magnetic storage devices away from the equipment because magnetically stored information may be corrupted by the magnetic field.

- Keep electronic devices, such as computers or monitors, away from the equipment because exposure to the magnetic field may result in malfunction or permanent damage to such devices.

Contact Eriez if you have a question regarding these precautions.

⚠️ CAUTION

Safety labels must be affixed to this product. Should the safety label(s) be damaged, dislodged or removed, contact Eriez for replacement.

Warning

Suspended electromagnets with self-cleaning belts are normally suspended above conveyor belts away from personnel working areas. Eriez has no control over this location or adjacent areas.

Under certain conditions it may be necessary for the user to install additional safety devices to protect operating personnel.

Suspended electromagnets with self-cleaning belts have pinch points where the belt goes over the pulleys. When the belt is running this is a hazardous area. Workers should be instructed not to perform duties on this equipment unless it is shut down and the electric supply source is locked out.

When either a self-cleaning or a manual cleaning electromagnet is energized, workers should never extend parts of their bodies into the magnetic field area between the conveyor and the magnet face. Tramp iron pieces will be attracted suddenly and unexpectedly to the magnet potentially pinning an arm etc. with enough force to cause severe injury. Warning and Caution plates and decals on the magnet must not be removed or painted over. It is important that these warnings and cautions be legible and that they be followed. Note the magnetic field warning at the front of this document.

---

FIGURE 2
Safety decal locations - self-cleaning models
Description

Suspended electromagnets are heavy duty DC powered separators designed for use over a moving bed of material from which iron is to be removed. Basically, they are box-shaped units with coils inside to generate a powerful magnetic field.

There are two basic types available: oil-cooled and air cooled. Both of these types are available as Manual or Self-Cleaning units. Each type has two styles, in-line and cross-belt, to accommodate installation requirements. There is a wide range of sizes available for each type and style.

Manual Cleaning magnets are designed for use where small amounts of tramp iron are suspected. They can be furnished with an adjustable cable sling designed for a one-point suspension or adjustable Jaw & Jaw turnbuckles for four-point suspension.

With Manual Cleaning magnets it is necessary to shut off the power periodically to discharge the accumulated tramp iron. Manual Cleaning Units may be installed over the head pulley or over the conveyor.

Self-Cleaning magnets consist of a Manual Cleaning unit with a short belt conveyor built around it to provide automatic discharge of tramp iron. These magnets, typically furnished with turnbuckles for four-point suspension, can also be used over the head pulley or over the conveyor.

FIGURE 3
Typical air-cooled self-cleaning suspended electromagnet

FIGURE 4
Typical oil-cooled manual cleaning suspended electromagnet
Installation

GENERAL
Use care in uncrating to avoid damage to the equipment.

IMPORTANT: Check the area upstream, downstream, on the sides and underneath the magnet for carbon steel or other ferrous metals. Specifically look for carbon steel conveyor belt idlers, slider beds, side frames or any other metals in the area. All carbon steel or ferrous metals within magnetic field of the magnet (up to 3-feet or possibly more for larger size magnets) will become induced or “magnetized” and will reduce the separation efficiency of the suspended electromagnet.

For this reason, replace all carbon steel or other ferrous metals with 304 or 316 stainless steel, aluminum, plastic, wood or other non-magnetic materials in the area of the magnet for the best magnetic separation efficiency.

For Oil-Cooled Models: Be sure the magnet is oriented properly. In all installations, the external oil expansion chamber must be at right angles to the direction of material flow and on the high side if installed at an angle. Magnets with adjustable expansion tanks must be positioned so the drain is at 6 o’clock. (See page 9). Check the pressure relief valve located on the high end of the oil expansion chamber to make sure it is free to operate. This is done by pulling the stem and releasing it. It is spring loaded and will re-seat itself when released.

MAGNET POSITIONS
Position 1 (in-Line)
The preferred installation of a suspended magnet is over the trajectory of material discharged from the belt conveyor. This is referred to as POSITION 1 (See Figures 5 and 6).

For optimum separation in Position 1 installations, provision must be made to adjust the location of the magnet to suit the trajectory of the material.

For Position 1 installations with conveyor belt speeds of less than 350 fpm (107 m/min), greater separation will be achieved by using a nonmagnetic head pulley.

If a Self-Cleaning unit is being installed, examine the area to make sure that the self-cleaning belt around the separator has adequate room to run properly and that provisions have been made to collect the discharged tramp iron. A hinged non-magnetic splitter, adjustable in length, will be required to prevent extracted tramp iron from reentering the product.

Position the magnet so that the face of the belt is approximately 2” (50 mm) from the trajectory of the material being discharged. The centerline of the magnet should be approximately perpendicular to the material at that point.

Position 2 (Cross-belt)
Installation of the separator over the moving bed of material at right angles to the conveyor is referred to as POSITION 2 (See Figures 7 and 8). This location normally presents a more difficult separation problem than Position 1 and usually requires a stronger magnet.

For Position 2 installations, steel conveyor idlers cannot be used in the length of the conveyor beneath the separator. Any conveyor idlers beneath the separator must be made of rubber, wood, or some other non-magnetic material. Both the Manual Cleaning and the Self-Cleaning units should be installed on the centerline of the material conveyor and parallel to the slope of the conveyor.
Specified suspension height should be considered a maximum and the magnet should be lowered as close to the actual burden as possible. When lowering the magnet to the burden, be sure that plowing of material does not occur. If the unit is a Self-Cleaning magnet, make sure that the separator belt has room to operate and discharge tramp iron properly. A clearance of 3" (75 mm) between the magnet or belt and the top of the burden is typical for Self-Cleaning units; this clearance can be reduced to 2" (50 mm) for Manual Cleaning units.

**BURDEN DEPTH**
The best separator performance is achieved by controlling the burden depth. A plow or leveler positioned above the conveyor and before the magnet will help level high spots or surges in Position 2 installations. For Position 1 installations, the recommended installation location is calculated on expected tonnage. Any variation from this rate changes the trajectory of the burden with respect to the working surface of the magnet and may result in poor separation.

**GUIDELINES FOR MAGNET INSTALLATION**
Generally, sufficient application data is available so that we can prepare an installation drawing to show the magnet location that will provide optimum tramp iron removal. However, for those instances where there is not enough information to permit preparation of a drawing, the guidelines that follow should be helpful. Observing these guidelines will not necessarily result in an ideal magnet location but as you approximate these conditions more closely, performance will be improved. It is important to provide for adjustment of the magnet position so optimum results can be obtained under actual operating conditions.

**Position 1 mounting - magnet over the conveyor head pulley.**
Determine where the highest point of the material trajectory occurs and position the magnet so that the face is 2" (50 mm) for a manual cleaning magnet and 3" (75 mm) if unit is self-cleaning type, above material and the magnet center line passes through the high point of the trajectory. See Figure 10.

---

**SUSPENSION HEIGHT**
Each size magnet is designed for a specific suspension height. This distance (See Figure 9) is measured from the magnet face to the product conveyor belt.

---

**FIGURE 7**
Manual cleaning position 2

**FIGURE 8**
Self-cleaning position 2

**FIGURE 9**
Suspension height
Installation (cont.)

**Note:** The normal magnet angle with respect to a horizontal plane will be in the range of 15-25°. As belt speeds increase, installation angles tend to decrease.

In cases where belt speeds are slower (usually 350 fpm (107 m/minute) or less) the material trajectory will not rise higher than the top of the pulley but, rather, will follow around the periphery of the pulley and “fall-off” the downstream side. For this condition, the magnet centerline should pass through the center of the pulley. **Note:** A head pulley of non-magnetic material (series 300 stainless steel) is required to avoid magnetic inducement that would be present with a mild steel pulley. See Figure 11.

**Position 2 mounting - magnet across the conveyor belt.**

Position the magnet so that it is centered over the width of the conveyor and the face (bottom) is parallel to the slope of the conveyor.

When a self-cleaning magnet is installed over a troughed conveyor belt, the magnet must be high enough so that a piece of iron on the magnet belt will clear the edge of the conveyor belt. However, caution must be exercised so that the rated suspension height of the magnet is not exceeded. See Figure 12.

**For Oil-Cooled Models:**

⚠️ **CAUTION**

After installation and prior to start-up, check the oil level at the Oil Level Plug located on the side corner of the magnet near the expansion tank. If the level is low, add oil of the type specified on the plate attached to the top of the magnet beside the Oil Fill Plug.

Oil Expansion Tanks are mounted with slotted brackets allowing adjustment to the tank. Adjustments are made to keep the relief valve in proper position.

Tanks can be factory adjusted if incline angle is specified when ordering. Otherwise field adjustment will be required.

Tanks are properly adjusted when the orientation arrow is pointing straight down. When hanging a magnet the tank is turned toward the magnet until the arrow points down.
**WIRING (CSA APPROVED)**

Wiring for Eriez electromagnets is very simple (see Figure 14). Connect the two DC leads from the DC power source to the two terminal posts in the magnet outlet box. A kit of crimp type terminal lugs is provided for the minimum recommended wire size for the magnet (refer to Table 5.)

The conductor insulation must be rated for 125°C. The CSA-Certified lugs are T&B (Thomas and Betts Co.) or equal and must be crimped with a T&B tool. A recommend T&B crimping tool is also listed for each conductor wire size in Table 5. Only use tools recommended by the terminal lug manufacturer. See Figure 15 for the routing of wires in the outlet box.

**CAUTION**

Do not attempt to turn the terminal posts themselves. This may result in internal damage.

Install the terminal lugs between the two brass nuts provided on the terminal posts. Hold the back nut securely in place with a wrench when tightening the front nut.

A ground stud is provided in the outlet box for the ground lug furnished in the kit of terminals. The ground lug is installed between the two brass nuts on the stud. The ground wire must be installed to the ground lug to be a CSA-approved installation.

**NOTE:** Either wire from the DC power source can be connected to either terminal post in the outlet box, unless indicated on the magnet. Do not break the DC leads from the DC power source with a switch or fuses. The energy from the magnet must have a decay path through the power source.
START-UP OF SELF-CLEANING UNITS

1. Be sure the frame is visibly square and has not been damaged or twisted.

2. After installation, momentarily close the AC switch to the belt drive to determine if the belt is running in the right direction. The bottom of the belt should be running toward the motor. Also check to see if the belt tends to wander and, if so, in which direction.

3. Belt Adjustment
   a. The smaller Suspended Electromagnets utilize a two-pulley design. The tail pulley has approximately 6" (150 mm) of take-up available for both belt stretch and tracking purposes. To track the belt, the tail pulley should be moved in a direction to tighten the belt on the side to which the belt wanders.
   b. The larger magnets have a four-pulley design and have two take-up adjustments. The bottom tail pulley is initially used to take up the slack (adjust both sides evenly). Tracking is achieved by adjusting the small pulley located on the same end so that the belt is tightened on the side to which it wanders.

NOTE: Never start the belt drive and allow it to run continuously until the belt is properly trained.

Maintenance

AIR-COOLED MANUAL CLEANING MODELS:
No maintenance other than periodic removal of tramp iron is required for air-cooled Manual Cleaning units.

OIL-COOLED MANUAL CLEANING MODELS:
1. The oil level should be checked periodically (check only when magnet is cold). If the oil level is low, fill as required with the same brand and type as noted on the plate beside the oil fill plug. Do not attempt to mix types since many substitutes for the original are not compatible.

2. The oil should be laboratory tested every 12 months for:
   a. Moisture
   b. Contaminants
   c. Dielectric strength (20 KV min.)

Eriez does not perform this service, but it is suggested that inquiries be directed to:
   a. a reliable testing laboratory
   b. the oil vendor
   c. local electric utility

3. Be sure the expansion tank pressure relief valve is free. This should be checked frequently. (See page 6 general installation instructions).

CAUTION
The relief valve can release hot oil if excessive heat causes above-normal expansion.

NOTE: Normal external operating temperature of Eriez oil-cooled electromagnets is approximately 185°F (85°C); for air-cooled magnets, approximately 160°F (70°C). These temperatures are extremely hot to the touch.

FOR SELF-CLEANING MODELS:
1. Lubricate bearings on a schedule consistent with other equipment in use with your product and environment. An NGL1 No. 2 lithium-base grease is recommended.

2. Check V-belt tension frequently. Adjust by tightening the reducer torque arm as required.

3. For motor and reducer maintenance, refer to the manufacturer’s instruction sheets packed with the shipment.

4. If the separator is to be installed inside a fabricated enclosure, provisions must be made to maintain and adjust moving parts as required.

5. After initial run in, check all fasteners for proper tightness. Refer to Torque Table on Page 14.

6. After 250 hours of running check pulley hubs and tighten set screws to 17 lb. ft. (23 Nm) torque.
7. Proper adjustment for belt tension and tracking is vital to trouble free operation of the self-cleaning system, and should be checked frequently. To track these belts you should proceed in the following manner:

The smaller Suspended Electromagnets utilize a two-pulley design. The tail pulley has approximately 6" (150 mm) of take-up available for both belt stretch and tracking purposes. To track the belt, the tail pulley should be moved in a direction to tighten the belt on the side to which the belt wanders.

The larger magnets have a four-pulley design and have two take-up adjustments. The bottom tail pulley is initially used to take up the slack (adjust both sides evenly). Tracking is achieved by adjusting the small pulley located on the same end so that the belt is tightened on the side to which it wanders.

8. Once the belt has been trained, further adjustment may be required to achieve proper tension. Excess tension applied in an effort to keep the belt flat against the face of the magnet can lead to pulley, shaft or bearing failure. It is normal for the belt to sag due to its own weight and this becomes more prevalent on the larger units. Efficient operation can be achieved without applying excess tension so the belt should be tightened only enough to prevent slipping on the pulleys when it is conveying iron off the face of the magnet. Usually a sag of up to 3" (75 mm) is not detrimental unless it interferes with material flow. See Figure 16.

![Belt is too tight](image1)

Belt is too tight

![Belt is too loose](image2)

Belt is too loose

![Belt should have 1" to 2" gap at magnet corners](image3)

Belt should have 1" to 2" gap at magnet corners. Larger magnets can have a belt sag in the center up to 3" (76 mm)

# Troubleshooting

**GENERAL**
On self-cleaning units, stop the belt before troubleshooting or performing checks and maintenance. Do not allow the belt to remain stationary for more than 30 minutes with the magnet energized; heat may damage the belt.

<td>Magnet will not attract iron</td>
<td>a. Magnet is not turned on or the magnet voltage is low&lt;br&gt;b. Magnet is not installed at the proper suspension height&lt;br&gt;c. Parts not being attracted are non-magnetic&lt;br&gt;d. Induced iron in the area of the magnet prohibits the extraction of tramp iron&lt;br&gt;e. Magnet is overheated&lt;br&gt;f. Magnet coils are grounded&lt;br&gt;g. Magnet coil is shorted or open</td>
<td>a. Check power switch and check DC voltage at magnet terminals; adjust as required&lt;br&gt;b. Check location of magnet with respect to burden and confirm that it is within the recommended suspension height at the centerline of the magnet&lt;br&gt;c. Check missed tramp iron with small permanent magnet to confirm that it is magnetic&lt;br&gt;d. Check area around the separator with a small steel probe to see if the structure or conveyor components are themselves acting as a magnet and attracting iron. Replace with a non-magnetic material as required&lt;br&gt;e. Check for proper DC voltage at the magnet terminals and check for proper current. Current should be approximately 30% lower than nameplate current. Correct voltage. Allow magnet to cool&lt;br&gt;f. Take megohm reading between each magnet terminal and ground. 0.5 megohms should be minimum reading&lt;br&gt;g. Check for rated current at rated voltage at magnet OR measure DC resistance of cold magnet. The resistance should equal the nameplate voltage divided by nameplate amperes</td>
</tr>
<tr>
<td>Oil Leak</td>
<td>a. Damaged unit&lt;br&gt;b. Excessive internal pressure</td>
<td>a. Check and repair as required. Magnet may be welded or patched as required BUT EXTREME CAUTION MUST BE TAKEN TO PREVENT FIRE DURING ANY WELDING in hazardous locations (coal dust, etc.). The welding should be performed by qualified welders using electric arc welding equipment. Drain the oil from the magnet into clean containers. Purge the magnet of all oil fumes by using an inert gas (argon or CO2). Purge for 30 to 45 min. through the drain plug in the magnet to the relief valve in the expansion tank at 5 pounds pressure. Continue to purge when welding. Small pin hole leaks can be more easily welded when peened shut first. A stainless steel plate or angle on a corner can be continuously welded over a crack if required. CARE should be taken when welding a magnet containing transformer oil to prevent igniting the oil in the magnet or any spilled oil. After welding is completed, check for leaks at 5 pounds pressure using soapy water. If no leaks are found, then fill the magnet with oil. Use a filter (paint filter) when re-installing oil to eliminate any ferrous particles to enter the magnet box which can cause coil failure&lt;br&gt;b. Check freedom of pressure relief valve and replace if required</td>

</tbody>
</table>

**TABLE 5**

**NOTES:**
1. The third digit in the model number denotes in line self cleaning (-1-), cross belt self cleaning (-2-), or manual cleaning (-3-).
   Example:  Model 7610 = In-line self-cleaning magnet
              Model 7620 = Cross-belt self-cleaning magnet
              Model 7630 = Manual clean magnet
2. Use grounding lug supplied in kit of terminal parts.
3. Each kit of terminals includes two listed terminal lugs and one ground lug.
